   Command line
2. **KeyVersionStore**
3. **Autocomplete**
4. **Image LRU**
5. **Excel**
6. **map digit to letter**

Lyft Onsite

In-Memory Key-Value Database

You are to build a data structure for storing integers. You will not persist the database to disk, you will store the data in memory.

For simplicity's sake, instead of dealing with multiple clients and communicating over the network, your program wil

Your database should accept the following commands.

SET <name> <value>
Set the variable name to the value value. Neither variable names nor values will contain spaces.

GET <name>
Print out the value of the variable name, or `NULL` if that variable is not set.

UNSET <name>
Unset the variable name, making it just like that variable was never set.

NUMWITHVALUE <value>
Print out the number of variables that are currently set to value. If no variables equal that value, print 0.

END
Exit the program. Your program will always receive this as its last command.

PART 2:
Once your database accepts the above commands and is tested and works, implement commands below

   Open a new transaction block. Transaction blocks can be nested (`BEGIN` can be issued inside of an existing

block) but you should get non-nested transactions working first before starting on nested. **A `GET` within a transaction returns the latest value by any command**. **Any data command that is run outside of a transaction block should commit immediately.**

- ROLLBACK

    Undo all of the commands issued in the most recent transaction block, and close the block. Print nothing if successful, or print `NO TRANSACTION` if no transaction is in progress.

- COMMIT

    Close all open transaction blocks, permanently applying the changes made in them. Print nothing if successful, or print `NO TRANSACTION` if no transaction is in progress.

Your output should contain the output of the GET and NUMWITHVALUE commands. GET will print out the value of the specified key, or NULL. NUMWITHVALUE will return the number of keys which have the specified value.

申请的是2019软件工程实习 找地里的大哥内推的 我分到的hr特别好 基本秒回邮件
一面是lc tag题 小哥就问了一道秒了聊了会儿天30分. more info on 1point3acres
终面是30min behavioral 90 min programming 60min 正常lc 也是问的tag题 但让我写了三个function细微改条件
签了nda我就不说lc是哪道题了 怕被认出来 好好刷面经就行 但是我把programming的原题贡献出来了
我个人认为我写的代码readability和correctness都是很好的 但是。。因为时间不够 某个function在list是空的时候忘记加return以至于
接下来会有idx out of range exception 也没来得及写comment 这里要骂一下我的面试官 30分钟我连题都没读懂问他一些example cases.
他说他也不知道 迟到了5分钟打来不说 还用了10+分钟问我简历 因为他找不到google docs的链接了 我最后快交的时候都急哭了 可定是negative signal
其实这道题地里我见过 但当时好多帖子就说的是什么kv store 而且只有一个帖子是提到了rollback,begin block功能我根本没看懂 还是希望大家贡献面经的时候说清楚点吧.
准备lyft准备了一周都没有去上课 最后就因为这个少加一句return跪了 哪怕再多给我2分钟我就查到了 心情堵的慌.

Command line

```
1  """
2  1. Start program: python myprogram.py
3  2. Type commands: "BEGIN", "ROLLBACK","COMMIT", "SET A 3", "UNSET A","GET A"
4  * Output will be printed to console.
5  * Add return statements for unit testing,not necessary but save code.
6

KeyVersionStore

Everytime we add a new key or change the value of that key, we increment the version.Return the value of a specific key in a specific version.

1. PUT <key> <value>

   Set the key name to the value. Key strings will not contain spaces. Print out the version number, the key and the value as PUT(#<version number>) <key> = <value> . The first write in the file should be version number 1 , the second should be version number 2 , etc.

2. GET <key>

   Print out the key and the last value of the key, or <NULL> if that key has never been set as in: GET <key> = <value>

3. GET <key> <version number>

   Print out the key, the version number and the value of key as it was at the time of the version number,

or `<NULL>` if that key was not set at that time, as in `GET <key>(#version) = <value>`. If the version number has not yet been recorded, return the most recent value for the key. See below for examples of formatted output.

51              print(result, file = output)
```

6. map digit to letter

第二题是用trie 就是给一个file 里面上半部分是单词下半部分是一些数字的组合

AA
WOT
YOU
ME
968
63
12345

要求output是

968: you, wot
63: me
12345: no result
. more info on 1point3acres
就是把数字对应的字母能组成的单词找出来，数字对应的是电话号码key pad上的character

```
from collections import defaultdict
class Trie():
    def __init__(self,val):
        self.val = val
        self.children = defaultdict(Trie)
        self.number = ""

def check(text):
    dic = {"A":2,
"B":2,"C":2,"D":3,"E":3,"F":3,"G":4,"H":4,"I":4,"J":5,"K":5,"L":5,"M":6,"N":6,"O":6,"P"
:7,"Q":7,"R":7,"S":7,
        "T":8,"U":8,"V":8,"W":9,"X":9,"Y":9,"Z":9}
    words = set()
    numbers = set()
```

```python
    with open(text) as f:
        content = f.readlines()
    content = [s.strip() for s in content if s]
    print(content)
    for w in content:
        if w.isupper():
            words.add(w)
        elif w.isdigit():
            numbers.add(w)
    root = Trie(0)
    res = defaultdict(list)
    print(words,numbers)
    for word in words:
        tmp = root
        for l in word:
            if l not in tmp.children:
                node = Trie(l)
                tmp.children[l] = node
                node.number = tmp.number+str(dic[l])
            tmp = tmp.children[l]

        if tmp.number in numbers:
            res[tmp.number].append(word)
    return res
```

Column | Value
A1 | 1
A2 | A1 + 4
A3 | A1 + A2 + 10
A1 | A3 - 5 (throw exception, because of circular reference. Remember: A3 was A1 + A2 + 10)

put('A1', '1')
put('A2', 'A1+4')
put('A3', 'A1+A2+10')
put('A3', 'A1 - 5') (throw exception, because of circular reference. Remember: A3 was A1 + A2 + 10)

Get('A1') => 1
Get('A2') => 5
Get('A3') => 16

第一轮90分钟上机coding：白人小哥，题目是设计excel，先讲思路，其实主要是处理dependency的问题，比如
A1=B1+C1, B1=D1+1这种情况如何处理。我的想法跟小白有点不一样，但也是work的，结果这个小白非要和我
追根问底，最后我就采用了小白的思路，尼玛这时候已经30分钟过去了。然后小白就走了，留下我一个人在那写
code。C++选手这时候就吃亏了，parse传进来的公式什么的就比较麻烦，小白你知道什么库的话可以随便用，但
我不知道，只能用string那些硬写，所以代码量还挺大的。到剩15分钟的小白又回来了，跟我讨论，让我解释我的
code，到这时候还有一块没写完，更别说测试代码了。最后提一句，我是用的他们的loan laptop写的，上面的gcc

编译器都不支持C++11，非常坑爹。

是A=B+C或A=B-C的格式，支持+-两种就行了，主要是这里B和C可以是常数或者表达式的，A必须是表达式，然后要自己处理string parse
